AniGame Hub – Anime and Gaming Media Tracker

AniGame Hub is a web application for people who watch anime and play video games. Users can create an account, search for anime or games, save titles to their profile, rate them, and track their progress. Each title can be marked as Watched/Played, In Progress, Plan To Watch/Play, or Dropped. Users can also favorite titles and share a public profile link so other people can view their lists, ratings, and current activity.

The main users are anime fans and gamers. The application will have a dashboard that shows saved media, favorites, current progress, and recently updated titles. A search page will let users browse anime and games from external APIs. These APIs will provide information such as titles, cover images, descriptions, genres, release dates, episode counts, and gaming platforms.

The user interface will be built with React, Next.js, and TypeScript. React will handle the interactive parts of the site such as media cards, search results, rating controls, progress tracking, and user profiles. Next.js will handle the main application structure and server-side features, while TypeScript will be used throughout the frontend and backend.

For the database and user accounts, the application will use Supabase. Supabase provides a PostgreSQL database, authentication, and backend services in one platform. It will store user accounts, saved anime and games, ratings, favorites, progress, and profile settings. The full anime and game catalogs will not be stored in Supabase. Instead, the application will save the external API ID of each title along with the user's personal data for that title.

The anime and game catalogs will come from external APIs such as AniList or Jikan for anime and RAWG or IGDB for games. This allows the application to search a large catalog without manually entering every title.

Overall, AniGame Hub combines anime and gaming tracking into one platform with user accounts, a searchable catalog, ratings, progress tracking, favorites, recommendations, and public profile sharing. The main technologies will be React, Next.js, TypeScript, Supabase, and external anime and gaming APIs.
